IN THE UNITED STATES PATENT AND TRADEMARK OFFICE

Docket No. AT9-99-234

11-12-99

Assistant Commissioner for Patents  
Washington, D.C. 20231

Sir:

Transmitted herewith for filing is the patent application of  
Inventor(s):

Carl Phillip Gusler  
Rick A. Hamilton, II

For: ENHANCED BACKUP AND RECOVERY METHODOLOGY

jc675 U.S. PTO  
09/439054  
11/12/99

Enclosed are also:

- ☒ 34 Pages of Specification including an Abstract
- ☒ 5 Pages of Claims
- ☒ 55 Sheet(s) of Drawings
- ☒ A Declaration and Power of Attorney
- ☒ Form PTO 1595 and assignment of the invention to IBM Corporation

CLAIMS AS FILED

FOR	Number Filed	Number Extra	Rate	Basic Fee (\$760)
Total Claims	33	-20	13 X \$ 18	= \$234.00
Independent Claims	3	-3 =	0 X \$ 78	= \$0
Multiple Dependent Claims	0		X \$260	= \$0
Total Filing Fee				= \$994.00

- ☒ Please charge \$994.00 to IBM Corporation, Deposit Account No. 09-0447.
- ☒ The Commissioner is hereby authorized to charge payment of the following fees associated with the communication or credit any over payment to IBM Corporation, Deposit Account No. 09-0447. A duplicate copy of this sheet is enclosed.
- ☒ Any additional filing fees required under 37CFR § 1.16.
- ☒ Any patent application processing fees under 37CFR § 1.17.

Respectfully,

David A. Mims, Jr.

**ENHANCED BACKUP AND RECOVERY METHODOLOGY**

5

**BACKGROUND OF THE INVENTION****1. Technical Field:**

10 The present invention relates to information processing technology. More particularly, the present invention relates to providing means for improving the efficiency and reliability in backing up data.

**2. Description of Related Art:**

15 The UNIX operating system is a multi-user operating system supporting serial or network connected terminals for more than one user. It supports multi-tasking and a hierarchical directory structure for the organization and maintenance of files. UNIX is portable, requiring only  
20 the kernel (<10%) written in assembler, and supports a wide range of support tools including development, debuggers, and compilers.

The UNIX operating system consists of the kernel, shell, and utilities. The kernel schedules tasks, manages  
25 data/file access and storage, enforces security mechanisms, and performs all hardware access. The shell presents each user with a prompt, interprets commands typed by a user, executes user commands, and supports a custom environment for each user. Finally, the utilities  
30 provide file management (rm, cat, ls, rmdir, mkdir), user management (passwd, chmod, chgrp), process management (kill, ps), and printing (lp, troff, pr).

A multi-user operating system allows more than one

Docket No. AT9-99-234

user to share the same computer system at the same time. It does this by time-slicing the computer processor at regular intervals between the various people using the system. Each user gets a set percentage of some amount of time for instruction execution during the time each user has the processor. After a user's allotted time has expired, the operations system intervenes, saving the program's state (program code and data), and then starts running the next user's program (for the user's set percentage of time). This process continues until, eventually, the first user has the processor again.

It takes time to save/restore the program's state and switch from one program to another (called dispatching). This action is performed by the kernel and must execute quickly, because it is important to spend the majority of time running user programs, not switching between them. The amount of time that is spent in the system state (i.e., running the kernel and performing tasks like switching between user programs) is called the system overhead and should typically be less than 10%.

Switching between user programs in main memory is done by part of the kernel. Main system memory is divided into portions for the operating system and user programs. Kernel space is kept separate from user programs. Where there is insufficient main memory to run a program, some other program residing in main memory must be written out to a disk unit to create some free memory space. A decision is made about which program is the best candidate to swap out to disk. This process is called swapping.

When the system becomes overloaded (i.e., where there are more people than the system can handle), the operating system spends most of its time shuttling programs between

Docket No. AT9-99-234

main memory and the disk unit, and response time degrades.

In UNIX operating systems, each user is presented with a shell. This is a program that displays the user prompt, handles user input, and displays output on the terminal. The shell program provides a mechanism for  
5 customizing each user's setup requirements, and storing this information for re-use (in a file called .profile).

When the UNIX operating system starts up, it also starts a system process (getty) which monitors the state  
10 of each terminal input line. When getty detects that a user has turned on a terminal, it presents the logon prompt; and once the password is validated, the UNIX system associates the shell program (such as sh) with that terminal (typically there are a number of different shells  
15 including ksh and csh). Each user interacts with sh, which interprets each command typed. Internal commands are handled within the shell (set, unset); external commands are invoked as programs (ls, grep, sort, ps).

Multi-tasking operating systems permit more than one  
20 program to run at once. This is done in the same way as a multi-user system, by rapidly switching the processor between the various programs. OS/2, available from IBM Corporation, One New Orchard Road, Armonk, NY 10504; and Windows 95, available from Microsoft Corporation, One  
25 Microsoft Way, Redmond, WA 98052, are examples of multi-tasking single-user operating systems. UNIX is an example of a multi-tasking multi-user operating system. A multi-user system is also a multi-tasking system. This means that a user can run more than one program at once,  
30 using key selections to switch between them. Multi-tasking systems support foreground and background tasks. A foreground task is one the user interacts

Docket No. AT9-99-234

directly with using the keyboard and screen. A background task is one that runs in the background (i.e., It does not have access to the screen or keyboard.). Background tasks include operations like printing, which can be spooled for  
5 later execution.

The role of the operating system is to keep track of all the programs, allocating resources like disks, memory, and printer queues as required. To do this, it must ensure that one program does not get more than its fair  
10 share of the computer resources. The operating system does this by two methods: scheduling priority, and system semaphores. Each program is assigned a priority level. Higher priority tasks (like reading and writing to the disk) are performed more regularly. User programs may  
15 have their priority adjusted dynamically, upwards or downwards, depending upon their activity and available system resources. System semaphores are used by the operating system to control system resources. A program can be assigned a resource by getting a semaphore (via a  
20 system call to the operating system). When the resource is no longer needed, the semaphore is returned to the operating system, which can then allocate it to another program.

Disk drives and printers are serial in nature. This  
25 means that only one request can be performed at any one time. In order for more than one user to use these resources at once, the operating system manages them via queues. Each serial device is associated with a queue. When a user program wants access to the disk, for example,  
30 it sends the request to the queue associated with the disk. The operating system runs background tasks (called daemons), which monitor these queues and service requests

Docket No. AT9-99-234

from them. A request is then performed by this daemon process, and the results are sent back to the user's program.

Multi-tasking systems provide a set of utilities for  
5 managing processes. In UNIX, these are ps (list  
processes), kill (kill a process), and & (run a process in  
the background). In UNIX, all user programs and  
application software use the system call interface to  
access system resources like disks, printers, memory etc.  
10 The system call interface in UNIX provides a set of system  
calls (C functions). The purpose of the system call  
interface is to provide system integrity. As all low  
level hardware access is under control of the operating  
system, this prevents a program from corrupting the  
15 system.

The operating system, upon receiving a system call,  
validates its authenticity or permission, then executes it  
on behalf of the program, after which it returns the  
results. If the request is invalid or not authenticated,  
20 then the operating system does not perform the request but  
simply returns an error code to the program. The system  
call is accessible as a set of 'C' functions, as the  
majority of UNIX is also written in 'C'. Typical system  
calls are: \_read - for reading from the disk unit; \_write  
25 - for writing to the disk unit; \_getch - for reading a  
character from a terminal; \_putch - for writing a  
character to the terminal; and \_ioctl - for controlling  
and setting device parameters.

The fundamental structure that the UNIX operating  
30 system uses to store information is the file. A file is a  
sequence of bytes, typically 8 bits long, and is  
equivalent to a character. UNIX keeps track of files

Docket No. AT9-99-234

internally by assigning each one a unique identifying number. These numbers, called i-node numbers, are used only within the UNIX operating system kernel itself. While UNIX uses i-node number to refer to files, it allows  
5 users to identify each file by a user-assigned name. A file name can be any sequence containing from one to fourteen characters.

There are three types of files in the UNIX file system: (1) ordinary files, which may be executable  
10 programs, text, or other types of data used as input or produced as output from some operation; (2) directory files, which contain lists of files; and (3) special files, which provide a standard method of accessing I/O devices.

15 UNIX provides users with a way of organizing files. Files may be grouped into directories. Internally, a directory is a file that contains the names of ordinary files and other directories, and their corresponding i-node numbers. Given the name of a file, UNIX looks in  
20 the file's directory and obtains the corresponding i-node number for the file. With this i-node number, UNIX can examine other internal tables to determine where the file is stored and make it accessible to the user. UNIX directories themselves have names, each of which may also  
25 contain fourteen characters.

Just as directories provide a means for users to group files, UNIX supports the grouping of directories into a hierarchical file system. At the very top of a hierarchy is a directory. It may contain the names of  
30 individual files and the names of other directories. These, in turn, may contain the names of individual files and still other directories, and so on. A hierarchy of

Docket No. AT9-99-234

files is the result. The UNIX file hierarchy resembles an upside-down tree, with its root at the top. The various directories branch out until they finally trace a path to the individual files, which correspond to the tree's

5 leaves. The UNIX file system is described as "tree-structured," with a single directory. All the files that can be reached by tracing a path down through the directory hierarchy from the root directory constitute the file system.

10 UNIX maintains a great deal of information about the files that it manages. For each file, the file system keeps track of the file's size, location, ownership, security, type, creation time, modification time, and access time. All of this information is maintained  
15 automatically by the file system as the files are created and used. UNIX file systems reside on mass storage devices such as disk files. These disk files may use fixed or removable type media, which may be rigid or flexible. UNIX organizes a disk as a sequence of blocks,  
20 which compose the file system. These blocks are usually either 512 or 2048 bytes long. The contents of a file are stored in one or more blocks, which may be widely scattered on the disk.

An ordinary file is addressed through the i-node  
25 structure. Each i-node is addressed by an index contained in an i-list. The i-list is generated based on the size of the file system, with larger file systems generally implying more files and, thus, larger i-lists. Each i-node contains thirteen 4-byte disk address elements.  
30 The direct i-node can contain up to ten block addresses. If the file is larger than this, then the eleventh address points to the first level indirect block. Address 12 and

Docket No. AT9-99-234

address 13 are used for second level and third level indirect blocks, respectively, with the indirect addressing chain before the first data block growing by one level as each new address slot in the direct i-node is  
5 required.

All input and output (I/O) is done by reading the writing files, because all peripheral devices, even terminals, are files in the file system. In a most general case, before reading and writing a file, it is  
10 necessary to inform the system of your intent to do so by opening the file. In order to write to a file, it may also be necessary to create it. When a file is opened or created (by way of the 'open' or 'create' system calls), the system checks for the right to do so and, if all is  
15 well, returns a non-negative integer called a file descriptor. Whenever I/O is to be done on this file, the file descriptor is used, instead of the name, to identify the file. This open file descriptor has associated with it a file table entry kept in the "process" space of the  
20 user who has opened the file. In UNIX terminology, the term "process" is used interchangeably with a program that is being executed. The file table entry contains information about an open file, including an i-node pointer for the file and the file pointer for the file,  
25 which defines the current position to be read or written in the file. All information about an open file is maintained by the system.

In conventional UNIX systems, all input and output is done by two system calls, 'read' and 'write,' which are  
30 accessed from programs having functions of the same name. For both system calls, the first argument is a file descriptor. The second argument is a pointer to a buffer

Docket No. AT9-99-234

that serves as the data source or destination. The third argument is the number of bytes to be transferred. Each 'read' or 'write' system call counts the number of bytes transferred. On reading, the number of bytes returned may  
5 be less than the number requested, because fewer than the number requested remain to be read. A return value of zero implies end of file, a return value of -1 indicates an error of some sort. For writing, the value returned is the number of bytes actually written. An error has  
10 occurred if this is not equal to the number which was supposed to be written.

The parameters of the 'read' and 'write' system calls may be manipulated by the application program that is accessing the file. The application must, therefore, be  
15 sensitive to and take advantage of the multi-level store characteristics inherent in a standard system memory hierarchy. It is advantageous, from the application perspective, if the system memory components can be viewed as a single level hierarchy. If this is properly done,  
20 the application could dispense with most of the I/O overhead.

One advantage of using a UNIX based operating system over other operating systems is that data can be isolated or segregated into different volume groups (VGs). The  
25 omnipresent "rootvg" contains the operating system details, and it is from this volume group that the computer runs. Similarly, data or application volume groups can also be created. The advantage of such volume groups is that, unlike competitive operating systems, an  
30 upgrade to a UNIX based operating system will only impact the rootvg, and will not affect application data. Analogously, application upgrades will not impact the

Docket No. AT9-99-234

operating system in any way, presuming that the application has been segregated into its own VG.

Faults are inevitable in digital computer systems due to such things as the complexity of the circuits and the associated electromechanical devices. To permit system operation, even after the occurrence of a fault, the art has developed a number of fault-tolerant designs. Improved fault-tolerant digital data processing systems include redundant functional units, e.g., duplicate CPUs, memories, and peripheral controllers interconnected along a common system bus. Each of a pair of functional units responds identically to input received from the bus. In the outputs, if a pair of functional units do not agree, that pair of units is taken off-line, and another pair of functional units (a "spare") continues to function in its place.

Even with the recent developments in fault-tolerant systems, there are characteristics of UNIX systems that make them difficult to adapt to conventional fault-tolerant operation. An important element of fault-tolerant systems is a maintenance and diagnostic system that automatically monitors the condition (or "state") of functional units of the data processing system, particularly those that are more readily replaceable ("field replaceable units," or FRUs). The complexity of UNIX based systems requires that such fault-tolerant systems maintenance and diagnostic systems (or "state machines") have capabilities that require state-of-the-art systems maintenance and diagnostics systems.

Disk failure is the most common hardware failure in the storage system, followed by failure of adapters and

power supplies. Protection against disk failure primarily involves the configuration of the logical volumes. To protect against adapter and power supply failures, a popular configuration includes two adapters and at least one disk per adapter, with mirroring across adapters, without regard to the number of active blocks in the volume group. By mirroring the original data, copies are available in case of an interruption. Read efficiency is also improved because the logical volume manager is free to choose a less busy drive from which to read. RAID (redundant array of independent disks) is an alternative mirroring technique where data is striped block by (512-byte) block, but portions of several (not necessarily all) of the drives are set aside to hold parity information. This spreads the load of writing parity information more evenly.

In today's information systems (IS) environment, backup and recovery are frequently a subject of great complexity and, therefore, an area in which lapses may occur. For instance, on UNIX systems, file backup may be enacted via mksysb (accomplished directly by the operating system), via specialized backup and recovery software, such as ADSM (ADSTAR distributed storage network (ADSTAR is a registered trademark of IBM)), available from IBM, or via some method built directly into an application for backing up its own data sets. Quite often, administrators are familiar with the usage of these divergent techniques and, accordingly, enact multiple backup methods on a given system within a finite and regularly scheduled timeframe. The result is a chaotic backup plan, which requires great planning and care to ensure that all necessary filesystems are backed up in a timely and thoughtful manner.

Docket No. AT9-99-234

Typically, backup is accomplished using either a "one size fits all" approach, where all data needs are subject to the same backup method. Alternatively, the administrator grapples with the management of various tools in an ad hoc manner. Neither process is an efficient use of the system administrator's time nor does either provide adequate backup results for the systems under the administrator's control.

It would be advantageous to provide a framework for a more efficient means for backing up data using diverse techniques. It would also be advantageous to provide a means for reducing the reliance on the skill level of the system administrator for implementing system backups. It would be further advantageous to provide a more automated means for backing up systems, thereby relieving the system administrator of some of the time constraints involving system backup. Additionally, it would be advantageous to provide system administrators with an easy-to-use and flexible backup tool that allows administrators to backup systems anytime, regardless of system usage.

Docket No. AT9-99-234

### **SUMMARY OF THE INVENTION**

The present invention relates to a system and method  
5 for the automated backing up of filesystems. Initially, a  
table file is built which lists at least the filesystems  
to be backed up. It also may list the type of backup  
techniques to be used for a specific filesystem, the  
filesystem's logical location, and the number of copies to  
10 be made. The table file is checked for syntax and is then  
available for other routines. An automated script may be  
used for building the table, and then it may be manually  
edited if necessary.

**BRIEF DESCRIPTION OF THE DRAWINGS**

The novel features believed characteristic of the invention are set forth in the appended claims. The invention itself, however, as well as a preferred mode of use, further objectives and advantages thereof, will best be understood by reference to the following detailed description of an illustrative embodiment when read in conjunction with the accompanying drawings, wherein:

10       **Figure 1** is a pictorial representation of a distributed data processing system in which the present invention may be implemented;

15       **Figure 2** is a block diagram depicting a data processing system that may be implemented as a server in accordance with a preferred embodiment of the present invention;

**Figure 3** is a block diagram illustrating a data processing system in which the present invention may be implemented;

20       **Figure 4** is a flowchart of a process for building a table file;

**Figure 5** is a flowchart depicting the process for backing up filesystems using the backup selection table file created in **Figure 4**;

25       **Figure 6** is a flow chart depicting a process for resolving a backup problem when using a backup selection table file in accordance with a preferred embodiment of the present invention;

30       **Figures 7A - 7E** depict a script called "fscpbktab\_unlock.ksh", which will remove locks on the table file that prevent various backup operations from

Docket No. AT9-99-234

interfering with each other;

**Figures 8A - 8G** depict a script called "fscpbktab\_build.ksh", which will build the table file based on an inventory of the filesystems actually present;

5       **Figures 9A - 9G** depict a script called "fscpbktab\_check.ksh", which will check the table file for syntax and content errors;

10       **Figures 10A - 10E** depict a script called "fscpbk\_sync.ksh", which will detect mirrored logical volumes where mirrored partitions in the logical volume are stale;

**Figures 11A - 11H** depict a script called "fscpbk\_select.ksh" that will parse the table file and select filesystems for backup;

15       **Figures 12A - 12J** depict a script called "fscpbk\_back.ksh" that will parse the table file and perform the actual backup of filesystems; and

20       **Figures 13A - 13G** depict a script called "fscpbk\_merge.ksh" that will parse the table file and merge those filesystems that have been split into separate primary and alternate filesystems.

2025 RELEASE UNDER E.O. 14176

**DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT**

With reference now to the figures, **Figure 1** is a pictorial representation of a distributed data processing system in which the present invention may be implemented. Distributed data processing system **100** is a network of computers in which the present invention may be implemented. Distributed data processing system **100** contains a network **102**, which is the medium used to provide communications links between various devices and computers connected together within distributed data processing system **100**. Network **102** may include permanent connections, such as wire or fiber optic cables, or temporary connections made through telephone connections.

In the depicted example, a server **104** is connected to network **102** along with storage unit **106**. In addition, clients **108**, **110** and **112** also are connected to network **102**. These clients **108**, **110** and **112** may be, for example, personal computers or network computers. For purposes of this application, a network computer is any computer coupled to a network, which receives a program or other application from another computer coupled to the network. In the depicted example, server **104** provides data, such as boot files, operating system images, and applications to clients **108**, **110** and **112**. Clients **108**, **110** and **112** are clients to server **104**. Distributed data processing system **100** may include additional servers, clients, and other devices not shown.

In the depicted example, distributed data processing system **100** is the Internet, with network **102** representing a worldwide collection of networks and gateways that use

the TCP/IP suite of protocols to communicate with one another. At the heart of the Internet is a backbone of high-speed data communication lines between major nodes or host computers, consisting of thousands of commercial, government, education, and other computer systems that route data and messages. Of course, distributed data processing system **100** also may be implemented as a number of different types of networks, such as, for example, an intranet, a local area network (LAN), or a wide area network (WAN). **Figure 1** is intended as an example and not as an architectural limitation for the present invention.

Referring to **Figure 2**, a block diagram depicts a data processing system which may be implemented as a server, such as server **104** in **Figure 1**, in accordance with a preferred embodiment of the present invention. Data processing system **200** may be a symmetric multiprocessor (SMP) system including a plurality of processors **202** and **204** connected to system bus **206**. Alternatively, a single processor system may be employed. Also connected to system bus **206** is memory controller/cache **208**, which provides an interface to local memory **209**. I/O bus bridge **210** is connected to system bus **206** and provides an interface to I/O bus **212**. Memory controller/cache **208** and I/O bus bridge **210** may be integrated as depicted.

Peripheral component interconnect (PCI) bus bridge **214** connected to I/O bus **212** provides an interface to PCI local bus **216**. A number of modems may be connected to PCI bus **216**. Typical PCI bus implementations support four PCI expansion slots or add-in connectors. Communications links to network computers **108**, **110** and **112** in **Figure 1** may be provided through modem **218** and network adapter **220**

Docket No. AT9-99-234

connected to PCI local bus **216** through add-in boards. Additional PCI bus bridges **222** and **224** provide interfaces for additional PCI buses **226** and **228**, from which additional modems or network adapters may be supported. A  
5 memory-mapped graphics adapter **230** and hard disk **232** may also be connected to I/O bus **212** as depicted, either directly or indirectly.

With reference now to **Figure 3**, a block diagram illustrates a data processing system in which the present  
10 invention may be implemented. Data processing system **300** is an example of a client computer. Data processing system **300** employs a peripheral component interconnect (PCI) local bus architecture. Although the depicted example employs a PCI bus, other bus architectures, such  
15 as Micro Channel and ISA, may be used. Processor **302** and main memory **304** are connected to PCI local bus **306** through PCI bridge **308**. PCI bridge **308** also may include an integrated memory controller and cache memory for processor **302**. Additional connections to PCI local bus  
20 **306** may be made through direct component interconnection or through add-in boards. In the depicted example, local area network (LAN) adapter **310**, SCSI host bus adapter **312**, and expansion bus interface **314** are connected to PCI local bus **306** by direct component connection. In contrast,  
25 audio adapter **316**, graphics adapter **318**, and audio/video adapter **319** are connected to PCI local bus **306** by add-in boards inserted into expansion slots. Expansion bus interface **314** provides a connection for a keyboard and mouse adapter **320**, modem **322**, and additional memory **324**.  
30 SCSI host bus adapter **312** provides a connection for hard

Docket No. AT9-99-234

disk drive **326**, tape drive **328**, and CD-ROM drive **330**.

Typical PCI local bus implementations support three or four PCI expansion slots or add-in connectors.

5 An operating system runs on processor **302** and is used to coordinate and provide control of various components within data processing system **300** in **Figure 3**. The operating system may be a commercially available operating system such as a UNIX based operating system, AIX for instance, which is available from International Business  
10 Machines Corporation. "AIX" is a trademark of International Business Machines Corporation. Other operating systems include OS/2. An object oriented programming system, such as Java, may run in conjunction with the operating system and provide calls to the  
15 operating system from Java programs or applications executing on data processing system **300**. "Java" is a trademark of Sun Microsystems, Inc. Instructions for the operating system, the object-oriented operating system, and applications or programs are located on storage  
20 devices, such as hard disk drive **326**, and may be loaded into main memory **304** for execution by processor **302**.

Those of ordinary skill in the art will appreciate that the hardware in **Figure 3** may vary depending on the implementation. Other internal hardware or peripheral  
25 devices, such as flash ROM (or equivalent nonvolatile memory) or optical disk drives and the like, may be used in addition to or in place of the hardware depicted in **Figure 3**. Also, the processes of the present invention may be applied to a multiprocessor data processing system.

30 For example, data processing system **300**, if optionally configured as a network computer, may not

Docket No. AT9-99-234

include SCSI host bus adapter **312**, hard disk drive **326**,  
tape drive **328**, and CD-ROM **330**, as noted by dotted line  
**332** in **Figure 3**, denoting optional inclusion. In that  
case, the computer, to be properly called a client  
5 computer, must include some type of network communication  
interface, such as LAN adapter **310**, modem **322**, or the  
like. As another example, data processing system **300** may  
be a stand-alone system configured to be bootable without  
relying on some type of network communication interface,  
10 whether or not data processing system **300** comprises some  
type of network communication interface. As a further  
example, data processing system **300** may be a Personal  
Digital Assistant (PDA) device which is configured with  
ROM and/or flash ROM in order to provide nonvolatile  
15 memory for storing operating system files and/or  
user-generated data.

The depicted example in **Figure 3**, as well as  
above-described examples, are not meant to imply  
architectural limitations.

20 As discussed above, system administrators are faced  
with the task of being very familiar with a number of  
diverse backup methodologies in order to implement a  
coherent system for backing up the filesystems under the  
administrator's care. Often, administrators must be  
25 familiar with the usage of these divergent techniques and,  
accordingly, enact multiple backup methods on a given  
system within a finite and regularly scheduled time frame.  
This situation may lead to system administrators delaying  
backing up systems which the administrator is less  
30 familiar and/or is more difficult to implement due the  
uniqueness of the system backup scheme.

Docket No. AT9-99-234

Introduced into this environment, an ideal backup tool would be one that permits the operation of different backup utilities and allows them to be controlled from a single point of interaction. Furthermore, besides  
5 providing a concentration of diverse methods beneath the same control mechanism, an exemplary backup tool would also create a master list of filesystems to be backed up automatically; it would allow the administrator to select specific backup methodologies for each filesystem (or even  
10 exempt filesystems from backup); and it would perform an audit function to ensure that the administrator does not inadvertently corrupt the control file during such modifications.

A preferred embodiment of the present invention, as  
15 manifested in the discussion and figures below, provides a single point of administration for diverse backup methodologies, and it automatically creates and audits backup control tables. It also permits administrator customization to exempt or modify filesystem specifics.  
20 Furthermore, the enhanced backup and recovery system detailed herein can also work with mirrored filesystems, taking one copy offline to make backups and then re-merging the mirror when the backup is complete. A preferred embodiment of the present invention may, in  
25 varying degrees, be applicable to and extendible across a variety of operating systems. Therefore, the implementation of an automating method for filesystem backup of the preset invention is not limited to AIX or UNIX type operating systems but, instead, may be  
30 incorporated into any type of operating system. However, the exemplary embodiment described herein resides on a UNIX system; therefore, the description of this

Docket No. AT9-99-234

implementation pertains particularly to such computer systems.

An important feature of the present invention is the building of a backup selection table file or configuration table. This table file (in colon-delimited format similar to the /etc/inittab file) indicates which filesystems are to be backed up. For filesystems on mirrored logical volumes, it will indicate what to name the temporary filesystems and logical volumes that result from the split. In accordance with a preferred embodiment of the present invention, the filesystem backup selection table file may be formatted as:

bc:pfs:plv:c:afs:alv

where, "bc" (Backup Control) is one of the following:

xb -> AIX Backup (Level 0 AIX FS Backup)  
no -> No Backup (Skip filesystem)  
as -> ADSM Selective Backup  
ai -> ADSM Incremental Backup  
aa -> ADSM Archive

The backup control tells the system which backup technique to use for the filesystem designated on that table command line. "pfs" (Primary Filesystem) is the full path of the standard filesystem, and "plv" (Primary Logical Volume) is the AIX LV name of the logical volume containing the primary filesystem. "c" (Copies) relates to the number of AIX LVM copies of the logical volume containing the primary filesystem. The copy number must be numeric 1, 2 or 3 for AIX filesystems; however, other flavors of UNIX may support more or fewer copies. "afs" (Alternate Filesystem) is the full path of the mirror copy filesystem and must be unique. "alv" (Alternate Logical Volume) is the AIX LV name of the logical volume

Docket No. AT9-99-234

containing the alternate filesystem and must also be unique. An example of a mirrored home filesystem to be backed up using an AIX backup command:

```
xb:/home:hd1:2:/alt/home:altlvh
```

- 5        Each command line relates to a separate filesystem to be backed up, specifying the backup technique, the physical and logical locations of the filesystem, the number of mirror copies present for the logical volume and, finally, the physical and logical location where the
- 10       copies are to be located once they are made. An administrator may, at any time, edit any line on the backup selection table file, or may instead edit the entire table. However, during backing up operations where the table file is being used in a backup process, the
- 15       table is locked in order to avoid conflict between backup operations. Unlocking the table is possible for troubleshooting or fixing a problem with a backup operation. The table file uses a two stage lock to prevent inadvertant modification of the file and the
- 20       resulting possible disruption of backup operations. The first stage of the lock is the use of a separate lock file. The presence or absence of the lock file is used by the constituent programs to signal whether it is safe or appropriate to modify or manipulate the table file itself.
- 25       The second stage of the lock is the manipulation of file access permissions on the table file itself. During key periods, the table file permissions are set to prevent any other users or outside processes from reading, editing, deleting, or otherwise manipulating the table file.
- 30       During safe periods, the table file permissions are returned to nominal settings. Syntax is crucial to the proper parsing of the table file, so, in a preferred

Docket No. AT9-99-234

embodiment of the present invention, syntax must be checked before any script will accept data in the table file for processing.

In a preferred embodiment of the present invention,  
5 for the mirrored filesystems, it will be the temporary filesystems that are backed up, meaning that the backups will contain the names of the filesystems and directories of the temporary (alternate) filesystem, not the primary (active) filesystem. The table file (created by the  
10 "fscpbktab\_build.ksh" script below) is self documenting.

A flowchart depicting a process for building and managing a table file is depicted in **Figure 4**. The process begins with the table file being tested for accessibility (step **402**). If the table is locked, it is  
15 assumed that the backup process is currently underway and that it is not desired to change the table file and confuse backup operations in progress. It is also possible that the table file may remain locked in the event of a backup problem or hang state. In that case,  
20 the system administrator needs to be able to resolve the problem and release the table lock condition before the next backup operation. Therefore, the table file must be unlocked, allowing the system administrator access to the table file and other backup operations to be performed  
25 subsequent to the administrator fixing the bug (step **404**). Unlocking the table involves a number of steps for updating error logs and checking syntax for active commands within the table.

While it is possible to manually perform each of the  
30 steps in unlocking the table file, there is a high probability that additional errors may be created by

Docket No. AT9-99-234

manually unlocking the table. Therefore, in accordance with a preferred embodiment of the present invention, a script called "fscpbktab\_unlock.ksh" is shown in **Figures 7A through 7E**. Returning to step **404** in **Figure 4**, the process proceeds to the problem solving phase depicted in **Figure 6** below.

Returning to step **402**, assuming that a locked table is not found, the administrator may proceed with building or editing the table. First, it must be determined if a table is in existence (step **406**). If a table file exists, the process flows to step **412**, where a decision is made whether or not to edit the table. Returning to step **406**, if no table file exists, a decision is made whether to manually build the table (step **408**). If the decision is made to manually build the table file, then the table file is manually created (step **419**) and the process again returns to step **412**; otherwise, the table is built by invoking an automated table building script (step **410**).

In accordance with a preferred embodiment of the present invention, an automated table building script "fscpbktab\_build.ksh" is shown in **Figures 8A through 8G**. This script automatically builds the table file based on an inventory of the filesystems actually present. A default backup method will be the AIX command "backup by i-node," and will be set for each present filesystem. Once a table file has been built, the process again flows to step **412**, where a decision is made whether the system administrator is to edit the table file.

If the administrator intends to edit the table by hand, the process flows to step **414**, where the editing is performed. Editing the table file may include actions

such as selecting which filesystems to backup, deselecting filesystems not to backup, changing the backup technique, or designating a new unique path for a copy. Returning to step **412**, if no hand entry is needed, the table file is

5 checked for syntax and context errors (step **416**).

An error free table is crucial for successfully backing up the filesystems; therefore, a script has been developed for automatically checking the table file following entries in the table. In accordance with a  
10 preferred embodiment of the present invention, a next script called "fscpbktab\_check.ksh" is shown in **Figures 9A** through **9G**. This script checks the table file for syntax and content errors. The system administrator may use this script to check the table file after it has been  
15 automatically built or hand edited. Importantly, any scripts that use the table file will check the table file for syntax checking prior to using the file. If a script determines that a table file has been edited subsequent to the last syntax check, the script will not use the table  
20 file but will issue an error.

Once a syntax-free table file is available for the system, the administrator may invoke the backup tool for automatically backing up filesystems. Therefore, the backup tool for backing up the filesystems may be invoked  
25 anytime thereafter. An important benefit of the present invention is that all of the criteria needed for backing up the filesystems have been pre-assembled for the system administrator in the table file. The administrator is freed from the tedious tasks associated with determining  
30 which filesystems to back up and determining an appropriate backup method for each filesystem, as well as

performing the checks and validations needed to ensure compliance with a specific operating system. By tabulating the criteria needed for backing up filesystems in a script-usable form, the present invention gives the system administrator the flexibility to perform a backup operation any time it is convenient for the system administrator.

**Figure 5** is a flowchart depicting the process for backing up filesystems using the backup selection table file created in **Figure 4** above. The process begins by synchronizing the mirrored logical volumes (step **502**). Because stale partitions must be updated prior to backing up the system, the first step is to sync or re-sync the entire system, thereby eliminating any potential problems related to backing up stale data. In accordance with a preferred embodiment of the present invention, a next script called "fscpbk\_sync.ksh" is shown in **Figures 10A** through **10E**. The depicted script will detect mirrored logical volumes where mirrored partitions in the logical volume are stale. Stale logical volumes will be resynchronized and, thus, ready for backing up if they are selected for backup. When invoked, fscpbk\_sync.ksh re-syncs all stale logical volumes without regard to the filesystems specified in the backup selection table file.

Returning to the process depicted in **Figure 5**, a check is made to determine if applications are presently running (step **504**). This is depicted in the present embodiment as a separate step, because there might be some occasions when the data structure table file is relatively uncomplicated and the system administrator may perform backup operations with some confidence that the

Docket No. AT9-99-234

filesystems to be backed up are not being accessed or modified at backup time. In that case, the system administrator merely calls the table file (step **516**), selects filesystems to backup (step **518**), splits any  
5 mirrored filesystems (step **520**) and backs up the filesystems using the table file (step **518**).

However, as discussed above, an important advantage of the present invention is to relieve the system administrator of the burden of having to manually backup  
10 selected filesystems. Therefore, a preferred embodiment of the present invention is depicted in a script called "fscpbk\_back.ksh" shown in **Figures 12A** through **12J**. This script parses the table file and performs the actual filesystem backups. If applicable, it also merges those  
15 filesystems that have been split into separate primary (active) and alternate (inactive) filesystems. This script returns various error codes if it is unable to locate the table file or the filesystems, and/or if it is unable to backup or merge the filesystems.  
20 fscpbk\_back.ksh performs the filesystem backup by first calling the table file; thus, the system administrator is relieved of having to perform step **516**.

Returning to step **504**, in many cases the system administrator may not know for certain that a filesystem  
25 to be backed up will not be used during the time that the filesystem is being backed up. Filesystems that are available twenty-four hours a day are particularly difficult to schedule. Therefore, an administrator may instead freeze the running applications (step **506**) and  
30 call the table file (step **508**). The administrator then determines which filesystems to back up (step **510**).

Docket No. AT9-99-234

Practically speaking, because fscpbk\_back.ksh actually performs the filesystem backing up, what is being selected are filesystems which cannot safely be backed up in their present state, such as mirrored filesystems which are  
5 available twenty-four hours a day or are presently frozen. The system administrator splits all mirrored filesystems that might be in use at backup time, including the frozen filesystems (step 512).

In accordance with a preferred embodiment of the  
10 present invention, a script called "fscpbk\_select.ksh" is shown **Figures 13A** through **13G**. This script automatically parses the table file and selects filesystems that must be split for backup. Most importantly, it will split those filesystems that are mirrored into separate primary  
15 (active) and alternate (inactive) filesystems. This script will return various error codes if it is unable to locate the table file or the filesystems, and/or if it is unable to split the filesystems. By invoking fscpbk\_select.ksh, steps **508**, **510** and **512** are  
20 automatically performed by the script and, thus, the administrator is freed from those tasks. Furthermore, fscpbk\_select.ksh accesses the table file for the name of the temporary filesystems and logical volumes that result from the split.

25 Returning to **Figure 5**, frozen applications are thawed and allowed to continue at the point where they were frozen (step 514). The process can be further automated by devising script which looks for running applications, freezes them at a convenient point in their process cycle,  
30 calls and executes the fscpbk\_select.ksh script and, once fscpbk\_select.ksh returns the split filesystems, thaws the

Docket No. AT9-99-234

frozen file. One of ordinary skill in the art could easily create such a script using the above description of its functionality.

Once all filesystems are in condition (mirrored  
5 filesystems split) for backing up, the system administrator can proceed with the backup operation at any time (step **520**). Again, the script fscpbk\_back.ksh may be employed for automatically backing up the filesystems. The process then ends with the filesystems being backed  
10 up.

As alluded to above, when a problem occurs in the backup operation, the backup selection table file is most probably in need of editing. **Figure 6** is a flowchart depicting a process for resolving a backup problem when  
15 using a backup selection table file in accordance with a preferred embodiment of the present invention. The process begins with the detection of a backup problem (step **602**). The system administrator may then call the table file (step **604**) and determine if it is locked (step  
20 **606**). If not, the process flows to step **610**, where a determination is made whether the table file needs editing. On the other hand, if the table file is locked, it may be unlocked using the script fscpbktab\_unlock.ksh as described above (step **608**). The table file might also  
25 be manually unlocked.

Next, the determination is made as to whether the table file needs editing (step **610**). If the table file does not need to be edited, the process flows to step **614**, where any split filesystems that are present are merged,  
30 thus allowing the backup process on those filesystems to continue at a later time. Returning to step **610**, it is

Docket No. AT9-99-234

generally assumed that the table file itself may either contain an error or that a problematic backup operation might need to be temporarily unselected while the backup problem is being studied. This allows other backups to  
5 continue. If so, the table file is edited (step **612**). Once the table file has been edited, the process flows to step **614**, where the split filesystems are merged, allowing the backup process on those filesystems to continue at a later time.

10 Below are descriptions of preferred embodiments of scripts used in describing the present invention.

Referring to **Figures 7A** through **7E**, a script called "fscpbktab\_unlock.ksh" removes locks on the table file  
15 that prevent various backup operations from interfering with each other. This script is generally only used for diagnostic or problem solving purposes.

Referring to **Figures 8A** through **8G**, a script called "fscpbktab\_build.ksh" builds the table file based on an inventory of the filesystems actually present. The system  
20 administrator may then edit the table file to select which filesystems to backup or not to backup. The default backup method will be the AIX command "backup by inode." The backup usually creates what is called an AIX "stacked tape."

25 Referring to **Figures 9A** through **9G**, a script called "fscpbktab\_check.ksh" will check the table file for syntax and content errors. The system administrator may use this script to check the table file after it has been edited, to select which filesystems to backup.

30 Referring to **Figures 10A** through **10E**, a script called "fscpbk\_sync.ksh" will detect mirrored logical volumes

Docket No. AT9-99-234

where mirrored partitions in the logical volume are stale. Stale logical volumes will be resynchronized.

Referring to **Figures 11A** through **11H**, a script called "fscpbk\_select.ksh" will parse the table file and select  
5 filesystems for backup. Most importantly, it will split those filesystems that are mirrored into separate primary (active) and alternate (inactive) filesystems. This script will return various error codes if it is unable to locate the table file, the filesystems, and/or is unable  
10 to split the filesystems.

Referring to **Figures 12A - 12J**, a script called "fscpbk\_back.ksh", will parse the table file and perform the actual backup of filesystems. It will also merge those filesystems that have been split into separate  
15 primary (active) and alternate (inactive) filesystems. This script will return various error codes if it is unable to locate the table file or the filesystems, and/or if it is unable to backup or merge the filesystems.

Referring to **Figures 13A** through **13G**, a script called  
20 "fscpbk\_merge.ksh" will parse the table file and merge those filesystems that have been split into separate primary and alternate filesystems. This merge action is performed without backing up any data. This script is generally used only for diagnostic or problem solving  
25 purposes.

It is important to note that, while the present invention has been described in the context of a fully functioning data processing system, those of ordinary skill in the art will appreciate that the processes of the  
30 present invention are capable of being distributed in the form of a computer readable medium of instructions and a

Docket No. AT9-99-234

variety of forms, and that the present invention applies  
equally regardless of the particular type of signal  
bearing media actually used to carry out the distribution.  
Examples of computer readable media include recordable  
5 type media, such as floppy discs, hard disk drives, RAM,  
and CD-ROMs and transmission-type media, such as digital  
and analog communications links.

The description of the present invention has been  
presented for purposes of illustration and description but  
10 is not intended to be exhaustive or limited to the  
invention in the form disclosed. Many modifications and  
variations will be apparent to those of ordinary skill in  
the art. The embodiment was chosen and described in order  
to best explain the principles of the invention and the  
15 practical application, and to enable others of ordinary  
skill in the art to understand the invention for various  
embodiments with various modifications as are suited to  
the particular use contemplated.

662145660

Docket No. AT9-99-234

**CLAIMS:**

What is claimed is:

1. A data processing system implemented method for  
5 automating a filesystem backup process, comprising:  
    building a table file, wherein the table file  
    lists filesystems to be backed up;  
    accessing the table file; and  
    backing up a filesystem listed in the table  
10 file.
2. The method recited in claim 1, wherein the table file  
contains a backup technique to be used for backing up each  
listed filesystem.
- 15 3. The method recited in claim 2, wherein backing up  
further comprises using a backup technique listed in the  
table file.
- 20 4. The method recited in claim 1, wherein the table file  
further comprises a logical location of the filesystem to  
be backed up.
5. The method recited in claim 1, wherein the table file  
25 further comprises a logical location for at least one  
backup copy.
6. The method recited in claim 1, wherein the table file  
further comprises a number of copies to be created.
- 30 7. The method recited in claim 1, further comprising,  
prior to backing up the filesystem, splitting the

Docket No. AT9-99-234

filesystem on the basis of the filesystem being in use during backing up the filesystem.

8. The method recited in claim 1, further comprising,  
5 prior to backing up the filesystem, locking the table file.
9. The method recited in claim 8, further comprising:  
detecting an error in backing up the filesystem;  
10 unlocking the table file; and  
editing the table file.
10. The method recited in claim 1, further comprising,  
prior to backing up the filesystem, re-syncing logical  
15 volumes servicing the filesystems.
11. The method recited in claim 1, wherein building a table file is performed by an automated script.
- 20 12. The method recited in claim 1, wherein accessing a table file is a function performed by an automated script.
13. The method recited in claim 1, wherein backing up the filesystem is performed by an automated script.
- 25 14. The method recited in claim 9, wherein unlocking the table file is performed by an automated script.
15. The method recited in claim 10, wherein re-syncing  
30 logical volumes is performed by an automated script.
16. The method recited in claim 7, wherein splitting the

Docket No. AT9-99-234

filesystem is performed by an automated script.

17. A data processing system for automating a filesystem backup process, comprising:

- 5           building means for building a table file,  
          wherein the table file lists filesystems to be backed  
          up;  
          accessing means for accessing the table file;  
          and  
10          backing means for backing up a filesystem listed  
          in the table file.

18. The system recited in claim 17, wherein the table  
file contains a backup technique to be used for backing up  
15 each listed filesystem.

19. The system recited in claim 18, wherein backing up  
further comprises using a backup technique listed in the  
table file.

20          20. The system recited in claim 17, wherein the table  
file further comprises a logical location of the  
filesystem to be backed up.

25          21. The system recited in claim 17, wherein the table  
file further comprises a logical location for at least one  
backup copy.

22. The system recited in claim 17, wherein the table  
30 file further comprises a number of copies to be created.

23. The system recited in claim 17, further comprising:

Docket No. AT9-99-234

splitting means for splitting the filesystem on the basis of the filesystem being in use during backing up the filesystem.

5 24. The system recited in claim 17, further comprising:  
locking means for locking the table file.

25. The system recited in claim 24, further comprising:  
detecting means for detecting an error in  
10 backing up the filesystem;  
unlocking means for unlocking the table file;  
and  
editing means for editing the table file.

15 26. The system recited in claim 17, further comprising:  
re-syncing means for re-syncing logical volumes  
servicing the filesystems.

27. The system recited in claim 17, the building means  
20 for building a table file is an automated script.

28. The system recited in claim 17, wherein the accessing  
means for accessing a table file is by an automated  
script.

25 29. The system recited in claim 17, wherein the backing  
means for backing up the filesystem is an automated  
script.

30 30. The system recited in claim 25, wherein the unlocking  
means for unlocking the table file is an automated script.

Docket No. AT9-99-234

31. The system recited in claim 26, wherein the re-syncing means for re-syncing logical volumes is an automated script.

5

32. The system recited in claim 23, the splitting means for splitting the filesystem is an automated script.

33. A data processing system implemented computer program product for automating a filesystem backup process, comprising:

10

building instructions for building a table file, wherein the table file lists filesystems to be backed up;

15

accessing instructions for accessing the table file; and

backing instructions for backing up a filesystem listed in the table file.

20

## 5

## 10

15

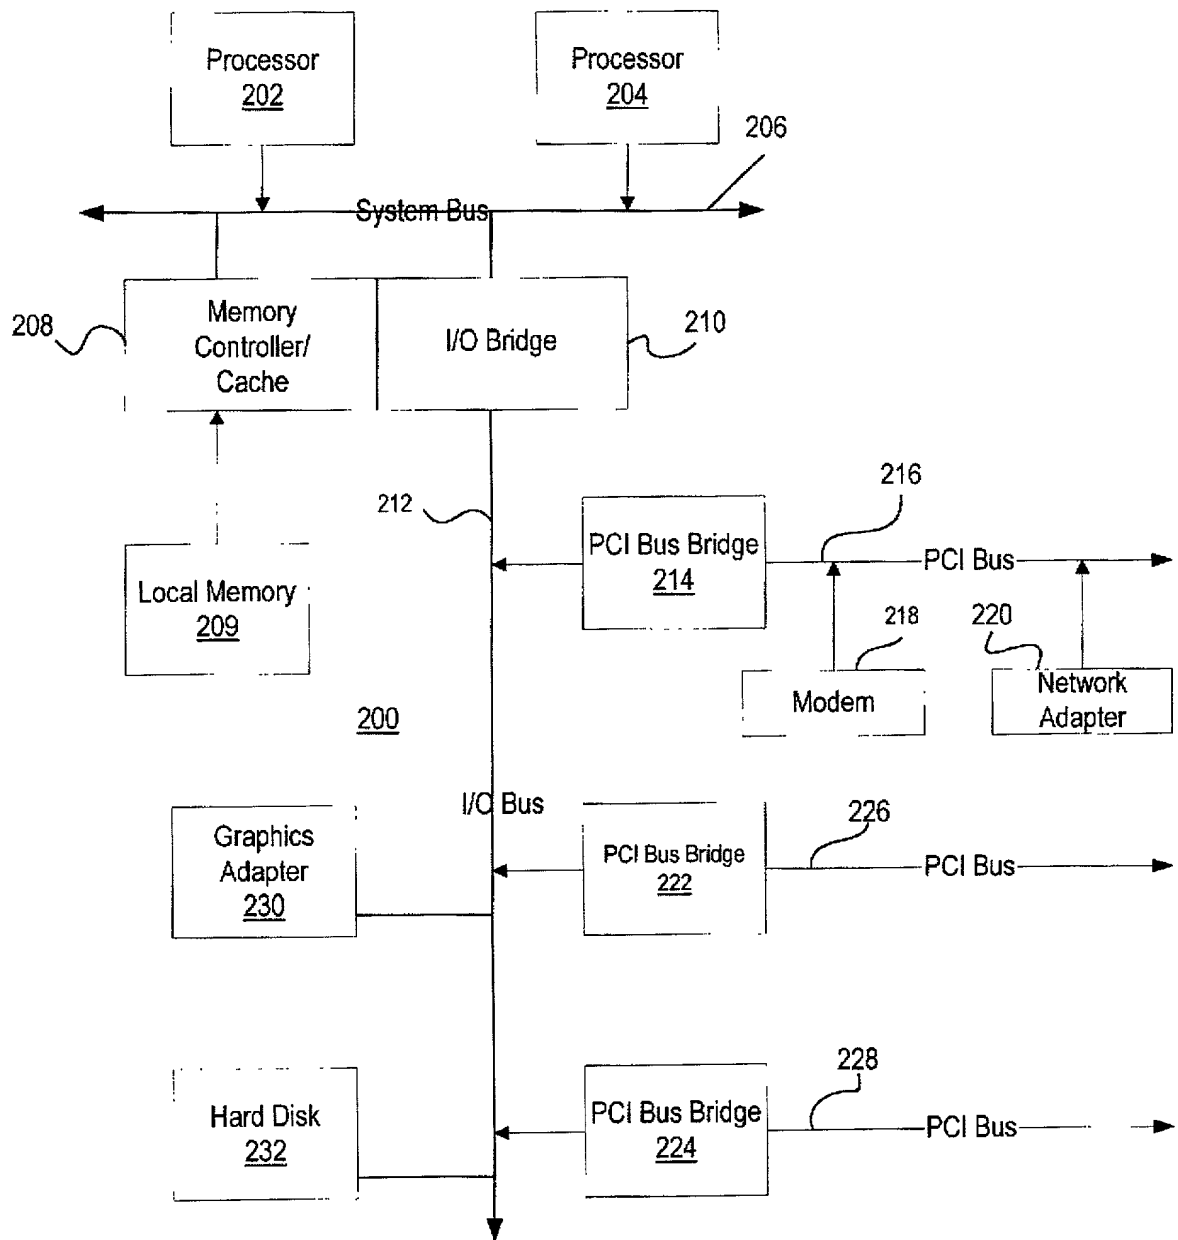

Initially, a table file is built which lists at least filesystems to be backed up. It also may list the type of backup techniques to be used for a specific filesystem, the filesystem's logical location, and the number of copies to be made. The table file is checked for syntax and is then available for other routines. An automated script may be used for building the table, and then it may be manually edited if necessary. Other scripts may be invoked for backing up the filesystems listed in the script by accessing the table file.

Figure 8D

AT9-99-234

1. *Chlorophyll a* (Chl *a*) is the primary photosynthetic pigment in most plants and algae. It is a green pigment that absorbs light energy in the blue and red regions of the visible spectrum. Chl *a* is essential for the light-dependent reactions of photosynthesis, where it converts light energy into chemical energy.

2. *Chlorophyll b* (Chl *b*) is an accessory pigment found in green plants and algae. It absorbs light energy in the blue and orange-red regions of the visible spectrum. Chl *b* transfers the absorbed energy to Chl *a*, which then uses it for photosynthesis.

3. *Carotenoids* are a group of pigments that include carotenes and xanthophylls. They absorb light energy in the blue and green regions of the visible spectrum. Carotenoids transfer energy to Chl *a* and also play a role in protecting the photosynthetic apparatus from damage by excess light energy.

4. *Xanthophylls* are a subset of carotenoids that include pigments like lutein and zeaxanthin. They absorb light energy in the blue and green regions of the visible spectrum. Xanthophylls are involved in the light-harvesting complex and also play a role in the xanthophyll cycle, which helps regulate the amount of light energy absorbed by the photosynthetic system.

5. *Anthocyanins* are water-soluble pigments that give plants red, purple, and blue colors. They are not directly involved in photosynthesis but can protect plants from damage by absorbing excess light energy and acting as antioxidants.

Figure 11F  
AT9-99-234

The first part of the paper discusses the importance of the research and the objectives of the study. The second part describes the methodology used, including the data sources and the statistical models employed. The third part presents the results of the analysis, showing the estimated effects of the variables on the dependent variable. The fourth part discusses the implications of the findings and provides some policy recommendations. The paper concludes with a summary of the main points and a list of references.

**DECLARATION AND POWER OF ATTORNEY FOR  
PATENT APPLICATION**

As a below named inventor, I hereby declare that:

My residence, post office address and citizenship are as stated below next to my name;

I believe I am the original, first and sole inventor (if only one name is listed below) or an original, first and joint inventor (if plural names are listed below) of the subject matter which is claimed and for which a patent is sought on the invention entitled

**ENHANCED BACKUP AND RECOVERY METHODOLOGY**

the specification of which (check one)

X is attached hereto.

\_\_\_\_\_ was filed on \_\_\_\_\_  
as Application Serial No. \_\_\_\_\_  
and was amended on \_\_\_\_\_  
(if applicable)

I hereby state that I have reviewed and understand the contents of the above identified specification, including the claims, as amended by any amendment referred to above.

I acknowledge the duty to disclose information which is material to the patentability of this application in accordance with Title 37, Code of Federal Regulations, §1.56.

I hereby claim foreign priority benefits under Title 35, United States Code, §119 of any foreign application(s) for patent or inventor's certificate listed below and have also identified below any foreign application for patent or inventor's certificate having a filing date before that of the application on which priority is claimed:

Prior Foreign Application(s):			Priority Claimed
_____ (Number)	_____ (Country)	_____ (Day/Month/Year)	___ Yes ___ No

I hereby claim the benefit under Title 35, United States Code, §120 of any United States application(s) listed below and, insofar as the subject matter of each of the claims of this application is not disclosed in the prior United States application in the manner provided by the first paragraph of Title 35, United States Code, §112, I acknowledge the duty to disclose information material to the patentability of this application as defined in Title 37, Code of Federal Regulations, §1.56 which occurred between the filing date of the prior application and the national or PCT international filing date of this application:

_____ (Application Serial #)	_____ (Filing Date)	_____ (Status)
---------------------------------	------------------------	-------------------

I hereby declare that all statements made herein of my own knowledge are true and that all statements made on information and belief are believed to be true; and further that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under Section 1001 of Title 18 of the United States Code and that such willful false statements may jeopardize the validity of the application or any patent issued thereon.

POWER OF ATTORNEY: As a named inventor, I hereby appoint the following attorneys and/or agents to prosecute this application and transact all business in the Patent and Trademark Office connected therewith.

John W. Henderson, Jr., Reg. No. 26,907; Thomas E. Tyson, Reg. No. 28,543; James H. Barksdale, Jr., Reg. No. 24,091; Casimer K. Salys, Reg. No. 28,900; Robert M. Carwell, Reg. No. 28,499; Douglas H. Lefevre, Reg. No. 26,193; Jeffrey S. LaBaw, Reg. No. 31,633; David A. Mims, Jr., Reg. 32,708; Volel Emile, Reg. No. 39,969; Anthony V. England, Reg. No. 35,129; Leslie A. Van Leeuwen, Reg. No. 42,196; Christopher A. Hughes, Reg. No. 26,914; Edward A. Pennington, Reg. No. 32,588; John E. Hoel, Reg. No. 26,279; Joseph C. Redmond, Jr., Reg. No. 18,753; Marilyn S. Dawkins, Reg. No. 31,140; Mark E. McBurney, Reg. No. 33,114; Duke W. Yee, Reg. No. 34,285; Colin P. Cahoon, Reg. No. 38,836; Joseph R. Burwell, Reg. No. 44,468; Rudolph J. Buchel, Reg. No. 43,448; and Stephen R. Loe, Reg. No. 43,757.

Send correspondence to: Duke W. Yee, Carstens, Yee & Cahoon, LLP, P.O. Box 802334, Dallas, Texas 75380, and direct all telephone calls to Duke W. Yee, (972) 362-2001.
